Keywords: Shallow ground water, Chemistry, Metals, Isotopes, Nutrients, Carbon, Simpevarp Sweden.

This report concerns a study which was conducted for SKB. The conclusions and viewpoints presented in the report are those of the author. SKB may draw modified conclusions, based on additional literature sources and/or expert opinions.

Data in SKB's database can be changed for different reasons. Minor changes in SKB's database will not necessarily result in a revised report. Data revisions may also be presented as supplements, available at www.skb.se.

A pdf version of this document can be downloaded from www.skb.se.

Abstract

In 2009 sampling of shallow ground water in water wells in soil has been performed in a regular programme at eight sites within the site investigation area at Oskarshamn. The purpose of the activity is to monitor (long term observation) and characterise the shallow ground water in the site investigation area.

Some physical and chemical parameters were measured directly in the field but most parameters were analysed at different laboratories. The ground water sampling activity consisted of one programme, chemical programme class 5 (reduced).

The large number of sites and parameters analysed have generated a large amount of data, which will later be used for advanced analysis and modelling. In this report the evaluation aims to give a simple overview of the results and to describe the quality of the data sampled 2009.

As an addition radon activity was measured at fourteen sites in the area. Seven of these sites were the same as in the regular programme.

The results showed a large variation between the wells. The concentrations of major ions and conductivity ranged from low to high or very high values. The concentration of HCO₃ also varied extensively throughout the investigation area, but since the concentrations were above 60 mg/l in most wells the results indicate a good ground water quality with respect to acidification.

The concentration of heavy metals and trace elements also varied. High concentration of Pb in some of the wells indicated pollution. Since Pb had a similar relation to Al as most other elements it was argued that high concentrations of lead probably can be explained by the natural composition of minerals within the site investigation area.

The ratio of δ¹⁸O showed a good relationship with the conductivity. The activity of tritium (³H) was markedly lower in two of the wells. This might be an indication of older groundwater in these wells. The average hydrogen isotope ratio of deuterium (δ²H) varied with similar values in most wells. The δ²H ratio correlates reasonably well with the δ¹⁸O ratio but the linear relation differ markedly from the “Global Meteoric Line” (δ²H = 8·δ¹⁸O+10) which is based on precipitation data.

The concentration of NO₃-N varied to some extent between the wells but according to the Swedish Environmental Quality Criteria the concentration was very low. The concentration of NH₄-N and PO₄-P varied with markedly higher values in some of the ground water wells. The site SSM000241 differed even more with extremely high values of NH₄-N and PO₄-P. The concentration of carbon (TOC and DOC) varied with low to moderately high concentrations in most wells. Again the well SSM000241 differed with very high concentrations.

Sammanfattning

Inom det reguljära programmet har provtagning av ytligt grundvatten i jordrör under 2009 skett vid åtta platser inom platsundersökningsområdet i Oskarshamn. Målsättningen med aktiviteten är att monitera (långtidsövervaka) och karakterisera det ytliga grundvattnet i området.

Några fysiska och kemiska parametrar har mätts direkt i fält men merparten av de insamlade parametrarna är resultatet av laboratorieanalyser. Aktiviteten bestod av ett program, klass 5 (reducerat).

Det stora antalet platser och analyserade parametrar har genererat en stor mängd data som senare kommer att användas för avancerad analys och modellering. I denna rapport har utvärderingen syftat till att ge en enkel översikt över resultaten och att beskriva kvaliteten av de data som samlats in 2009.

Resultaten av undersökningarna visade på en stor variation mellan de olika grundvattenrören i området. Halterna av joner och vattnets och konduktivitet varierade från låga till väldigt höga värden. Även halten av HCO_3 varierade mycket mellan provplatserna. På de flesta platserna var dock halterna över 60 mg/l vilket visar på en god vattenkvalitet med avseende på försurning.

Koncentrationerna av tungmetaller och spårelement varierade också relativt mycket mellan de olika provplatserna. En hög koncentration av Pb vid några av platserna indikerade föroreningspåverkan. Eftersom relationen mellan koncentrationen av Pb och Al liknade den som flertalet andra metaller och spårelement hade med Al drogs dock slutsatsen att de höga blyhalterna kan förklaras med mineralets naturliga sammansättning i området.

Isotopen $\delta^{18}\text{O}$ visade en god relation med konduktiviteten i vattnet. Medelvärdet för aktiviteten av tritium (${}^3\text{H}$) var märkbart lägre i två av jordrören vilket kan vara en indikation på att grundvattnet är äldre i dessa jordrör. Kvoterna av deuterium ($\delta^2\text{H}$) varierade med liknande värden i de flesta grundvattenrören. Kvoterna av $\delta^2\text{H}$ var relativt väl korrelerade med kvoterna av $\delta^{18}\text{O}$ men det linjära sambandet skiljde sig märkbart från "the Global Meteoric Line" ($\delta^2\text{H}=8 \cdot \delta^{18}\text{O}+10$) vilken baseras på data från nederbörd.

Koncentrationen av $\text{NO}_3\text{-N}$ varierade i viss grad men enligt Naturvårdsverkets kriterier var halterna mycket låga i samtliga grundvattenrör. Koncentrationen av $\text{NH}_4\text{-N}$ och $\text{PO}_4\text{-P}$ varierade med märkbart högre halter i några av jordrören. Resultaten från jordrören SSM000241 visade på vad som kan klassas som extremt höga halter av $\text{NH}_4\text{-N}$ och $\text{PO}_4\text{-P}$. Koncentrationen av kol (TOC och DOC) varierade med värden som kan betecknas som låga till måttligt höga i de flesta jordrören. Jordrören SSM000241 avvek med betydligt högre halter.

1 Introduction

This document reports the data gained by sampling of shallow ground water 2009, which is one of the activities performed within the site investigation programme at Oskarshamn. The work was carried out in accordance with the activity plan AP PS 400-09-002. In Table 1-1 controlling documents for performing this activity are listed. The activity plan is one of SKB's internal controlling documents.

Within the site investigation area water has been sampled from shallow ground water wells in soil. During 2009 sampling was performed in a regular programme at eight sites on four occasions (Figure 1-1). The water was analysed for a large number of parameters.

As an addition field measurement on radon activity was performed in May at fourteen sites in the area (Figure 1-1). Seven of these sites were the same as in the regular programme. Primary data from these measurements are presented in Appendix 4. Description of methods and a full evaluation of the results have been presented in the SKB report R-09-47 /Grolander 2009/.

Table 1-1. Controlling documents for the performance of the activity.

Activity plan	Number	Version
Hydrokemisk jordrörsmonitoring 2009	AP PS 400-09-002	1.0

All original results have been stored in the primary database SICADA. The results are traceable by the activity plan number. The data in the database will later be used for further interpretation (modelling).

2 Objective and scope

The purpose of the activity was to monitor and characterise the shallow ground water in the site investigation area. According to the activity plan sampling was planned to be performed at eight different ground water wells, at four occasions during 2009. Two of these water wells are situated in the Ävrö, Hålö and Simpevarp peninsula area, and the rest in the Laxemar area.

Some physical and chemical parameters were measured in the field and water samples for analysis of further parameters were sent to different analyzing laboratories for analysis.

In general the ground water sampling activity was done according to the programme chemical class 5 (reduced). Analysed parameters are presented in Table 2-1. If it was not possible to get a sufficient amount of water for analysis of all components a priority order was set up (Table 2-1). A time schedule for the sampling in 2009 is presented in Appendix 2.

The large number of sites and parameters analysed have generated a large amount of data, which will later be used for advanced analysis and modelling. In this report the evaluation aims to give a simple overview of the results and to describe the quality of the data sampled during 2009.

Table 2-1. Analysed components and priority order when sampling ground water wells 2009.

Components	Priority	Components	Priority
Alkalinity, pH, Conductivity	2	Fe ²⁺ , Fe-tot	7
Anions (F ⁻ , Cl ⁻ , Br ⁻ , SO ₄ ²⁻)	3	HS ⁻	8
Standard elements	1	NH ₄ , NO ₃ , NO ₂ , NO ₂ +NO ₃ , PO ₄	9
Heavy metals	1	Tot-N and Tot-P	10
Lantanoïdes	1	DOC	11
Trace elements	1	TOC	12
δ ² H, δ ¹⁸ O	4	POP, PON and POC	13
³ H	5	Archive (acid rinsed)	14
δ ³⁷ Cl	6	Archive	14

3 Equipment

3.1 Equipment used in the field

Underwater pump (type 12 V Avimex) or a 12 V vacuum pump was used for pumping up water from the ground water wells.

Two litres plastic cans were used as collecting vessels for archive samples. Acid rinsed 500 ml plastic vessels were used when sampling for analysis of Fe^{2+} , Fe (tot), standard elements, trace elements, lantanoïdes, and heavy metals. Archive samples were also taken from the acid rinsed vessels.

Samples for analysis of $\text{NH}_4\text{-N}$, $\text{NO}_2\text{-N}$, $\text{NO}_3\text{-N}$, $\text{NO}_2/\text{NO}_3\text{-N}$, $\text{PO}_4\text{-P}$ and DOC were filtered with disposable filters $0.45\mu\text{m}$.

Sounding apparatus, pH-meter and thermometer were used for field measurements.

3.2 Equipment used at the laboratory

A tube pump was used in the laboratory to filter sampled water.

A $0.45\mu\text{m}$ filter (PALL) Capsule filter was used together with the tube pump.

A $0.45\mu\text{m}$ membrane filter was used together with the tube pump.

4 Execution

4.1 Sites and sampling frequency

The total number of sampled sites was fifteen (Appendix 1). Eight of the sites were sampled according to the regular programme four times during 2009 for the parameters presented in Table 2-1. At fourteen of the sites field measurements of radon were performed in May (Appendix 1). This was done as an addition to the regular programme. The sampling frequency of the regular programme in 2009 is presented in Appendix 2.

4.2 Execution of sampling and treatment of samples

To avoid contamination all sampling was conducted with protective rubber gloves and great care was taken not to contaminate containers or equipment. The day before sampling, each ground water well was visited and water was pumped out, if possible, for at least 15 minutes. On the sampling day, the ground water level was sounded and noted. Field measurements of pH were then performed, before the collecting vessels were filled with water. The samples for analysis of NH₄-N, NO₂-N, NO₃-N, NO₂/NO₃-N, PO₄-P and DOC were filtered in field with a syringe and 0.45 µm filters.

Bottles for most analysis were filled and treated in the field (Table 4-1). Water for archive samples, Fe²⁺, Fe (tot), standard elements, trace elements, lantanides, and heavy metals were transported in collecting vessels to a preparation room where the samples were divided into smaller bottles and treatments were made (Table 4-1). All work was conducted with protective rubber gloves to minimise the risk of contamination.

Routines for storing and delivery of samples to the different analysing laboratories are presented in Table 4-2. Some of the samples were sent immediately at the end of each day and some were stored in a refrigerator till the end of the week, when they were sent to the laboratory.

Table 4-1. Field and indoor treatments of samples. Samples which are treated indoor are marked grey.

4.3 Documentation

All activities were continuously documented. Notes were taken on field conditions, time of sampling, markings of samples and so forth. Any deviations from the normal routines were also noted and commented in a special report. Delivery notes with instructions on which components to analyse were always sent with the samples to the different laboratories.

After analysis data has continuously been reported from the laboratories. As a routine a first preliminary quality control of the data was performed before storing them in the database SICADA.

5 Nonconformities

The water well SSM000241 was not possible to sample in November due to lack of water.

6 Results and discussion

6.1 Primary results

All primary results from the laboratory analysis and from the field measurements are presented in Appendix 3 and 4.

6.2 Dissolved ions and conductivity

The concentrations of ions and the conductivity varied much between the sites (Table 6-1). The sites with the highest concentrations of ions are situated close to the coast or under the seabed. The site SSM000042 which is situated quite far from the coast also had comparably high concentrations of ions.

According to the Swedish Environmental Quality Criteria /Naturvårdsverket 1999/ the concentrations of chloride ranged from low to very high at different wells, with concentrations above 100 mg/l termed as high and above 300 mg/l termed as very high.

As a quality control the charge balance has been calculated for the samples. In two of the samples there was a positive deviation of more than 10 percent (Table 6-2). This could indicate analytical problems or significant concentrations of negative ions which were not included in the calculation of the charge balance. These samples had a comparatively low conductivity which might be an indication of ions not included in the calculation instead of analytical errors (Figure 6-1). One possible example is organic anions which has not been included. In three cases (Table 6-2) there were negative deviations of more than ten percent. Likewise this could indicate either analytical problems or significant concentrations of positive ions not included in the calculation.

Table 6-1. Average concentration of major ions and conductivity in shallow ground water wells 2009.

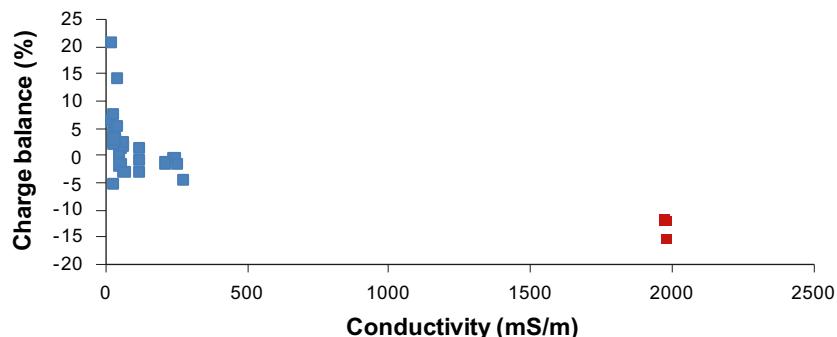

Figure 6-1. Relation of charge balance and conductivity in samples from all ground water wells 2009. Red dots show the site SSM000241.

6.3 Acidification

As with other ions the concentration of HCO_3 varied extensively throughout the investigation area (Table 6-3). In most of the wells the average concentration of HCO_3 was higher than 60 mg/l which is termed as a high or very high concentration according to the Swedish Environmental Quality Criteria /Naturvårdsverket 1999/. These results indicate a good ground water quality with respect to acidification at the investigated sites. The wells SSM000014 and SSM000041 differed with an average concentration of HCO_3 below 60 mg/l. This might indicate problem with acidification at these sites.

The field measurements of pH had a poor relation with the measurements in the laboratory (Figure 6-2). Likewise the field measurements of pH were poorly correlated to HCO_3 (Figure 6-3).

Table 6-3. Average concentration of HCO_3 , calculated alkalinity (HCO_3) and pH in shallow ground water wells 2009.

Site number	HCO_3 (mg/l)	Alkalinity (meq/l)	pH-lab	pH-field
SSM000014	39.5	0.647	6.10	6.33

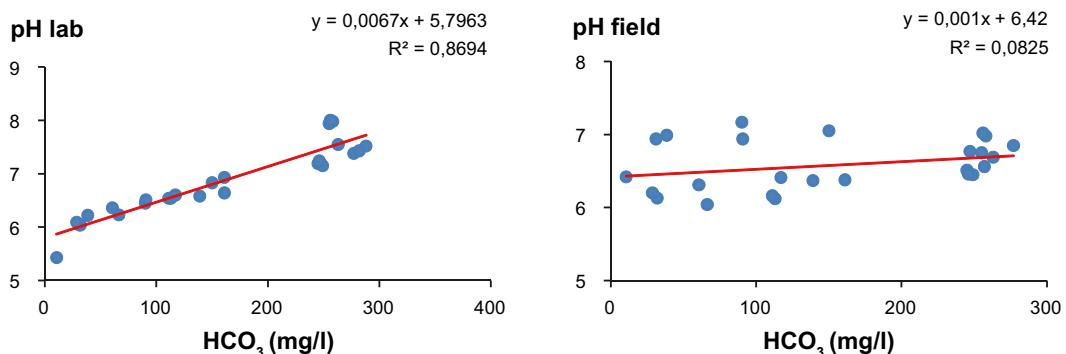

Figure 6-3. Relation of pH measured in the laboratory and HCO_3 and relation of pH measured in the field and HCO_3 in ground water wells 2009. Data from the well SSM000241 is not included.

6.4 Heavy metals and trace elements

The concentrations of heavy metals and trace elements are presented as averages in Table 6-4 and 6-5. The results varied quite much between the wells but most elements had a strong relation with aluminium, examples are shown in Figure 6-4. This indicates a good quality of the analysis performed. However, in two cases apparent outliers exist, indicating pollution, contamination or analytical errors. The cases are Zn (SSM000240 and SSM000241, sample numbers 15852 and 19049) (Figure 6-5). Similar outliers exists for some other elements at site SSM00241 (Figure 6-6). This ground water well seems to have a different type of water and therefore the poor relation with aluminium is probably not an indication of pollution, contamination or analytical errors.

Some of the heavy metals can be classified according to the Swedish Environmental Quality Criteria's /Naturvårdsverket 1999/. According to these criteria's the concentration of Cd and Zn was low to moderately high in the different wells. These results are what to be expected in an unpolluted area. However, the average concentration of Pb was very high ($> 10 \mu\text{g/l}$) in one well (SSM000014) (Table 6-4 and Figure 6-7). This could be an indication of some kind of pollution. However, since the relation to aluminium is similar to most other elements the high concentration of Pb in this well can probably be explained as a natural composition of the mineral at the site.

Table 6-4. Average concentration of heavy metals in shallow ground water wells 2009. Figures in italic indicate that some or all individual values in the calculation were below the report limit of the laboratory.

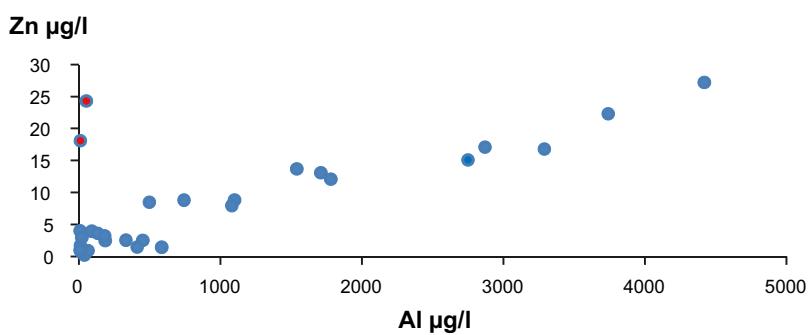

Figure 6-5. Relations between concentrations of Al and Zn in ground water wells 2009. Apparent outliers are marked red.

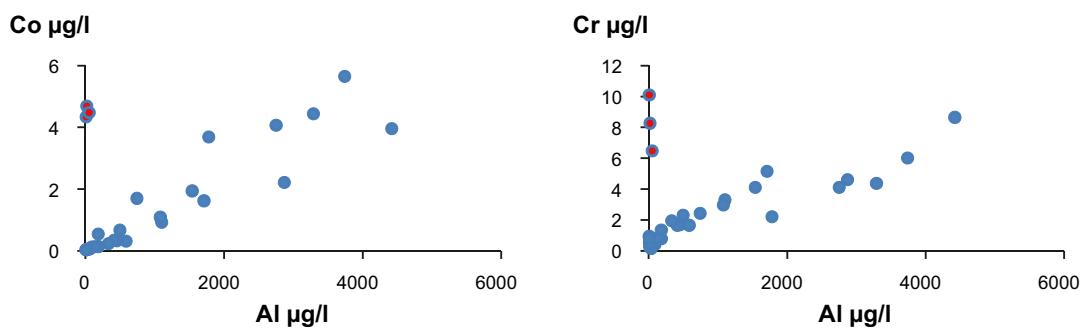

Figure 6-6. Relations between concentrations of Al and Co and Al and Cr in ground water wells 2009. Results from SSM00241 are marked red.

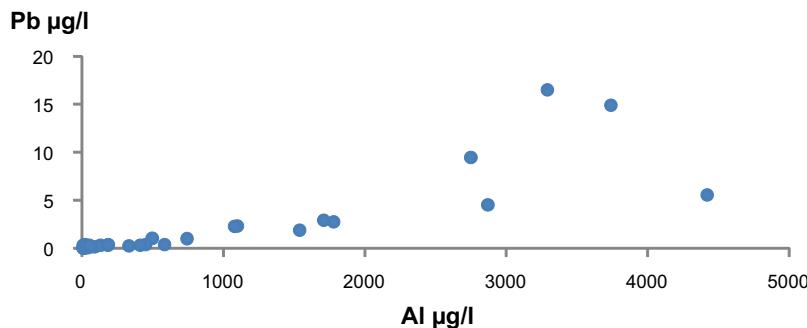

Figure 6-7. Relation between concentrations of Al and Pb in ground water wells 2009.

6.5 Isotopes

The results of the measurements of isotopes are presented in Table 6-6. The ratio of $\delta^{18}\text{O}$ showed a good relationship with the conductivity (Figure 6-8).

The activity of tritium (${}^3\text{H}$) was markedly lower in the wells SSM000022 and SSM000241. This might be an indication of older groundwater in these wells. The average hydrogen isotope ratio of deuterium ($\delta^2\text{H}$) varied with similar values in most wells. The $\delta^2\text{H}$ ratio correlates reasonable well with the $\delta^{18}\text{O}$ ratio but the linear relation differ from the “Global Meteoric Line” ($\delta^2\text{H}=8 \cdot \delta^{18}\text{O}+10$) which is based on precipitation data (Figure 6-9).

Table 6-6. Average ratio of $\delta^2\text{H}$, $\delta^{18}\text{O}$ and $\delta^{37}\text{Cl}$ and average activity of tritium in shallow ground water wells 2009.

Site number	$\delta^2\text{H}$ (‰ VSMOW)	$\delta^{18}\text{O}$ (‰ VSMOW)	${}^3\text{H}$ (TU)	$\delta^{37}\text{Cl}$ (‰ SMOC)
SSM000014	-69.0	-10.0	11.0	-
SSM000022	-73.5	-10.6	0.80	-

SSM000241	-62.4	-8.9	1.30	-0.353

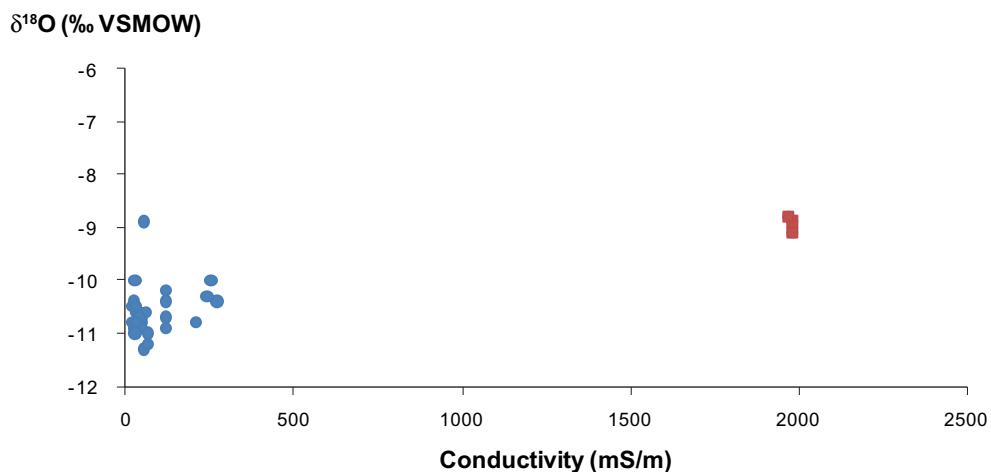

Figure 6-8. The relationship between the conductivity and the ratio of $\delta^{18}\text{O}$ in ground water wells 2009. Red dots show the site SSM000241.

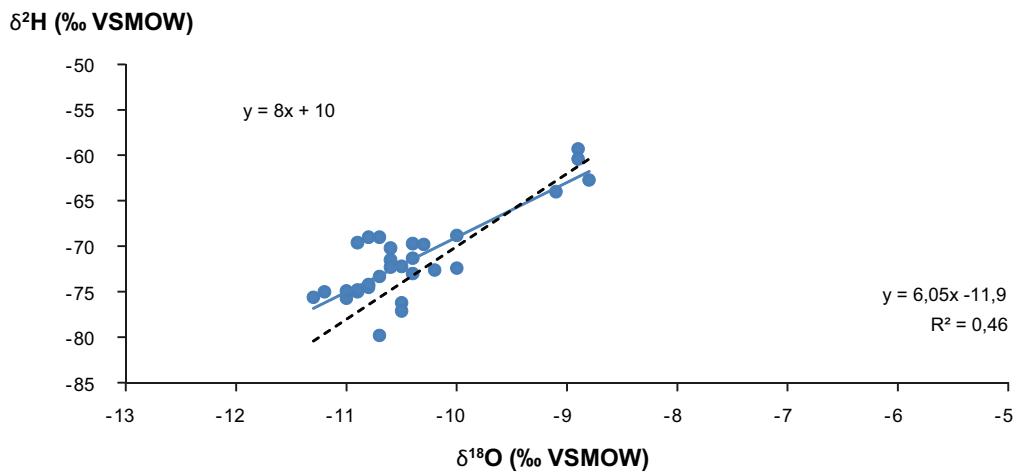

Figure 6-9. The local relationship between the ratios of $\delta^2\text{H}$ and $\delta^{18}\text{O}$ in ground water wells 2008. The dotted line shows "Global Meteoric Line" ($\delta^2\text{H} = 8 \cdot \delta^{18}\text{O} + 10$).

6.6 Nutrients and carbon

The concentration of nitrate varied to some extent between the wells (Table 6-7), but according to the Swedish Environmental Quality Criteria /Naturvårdsverket 1999/ the concentration of nitrate was very low in all the wells. The concentration of NH₄-N and PO₄-P varied with markedly higher values in some of the ground water wells. The site SSM000241 differed even more with extremely high values of NH₄-N and PO₄-P. The concentration of carbon (TOC and DOC) varied with results between 5 and 15 mg/l in most wells (Table 6-7). Again the well SSM000241 differed markedly with a markedly higher average.

Table 6-7. Average concentration of nitrogen and phosphorus compounds and carbon in shallow ground water wells 2009. Figures in italic indicate that some or all individual values in the calculation were below the report limit of the laboratory.
